Botulinum toxin (Botox) injection is a new and evolving treatment for migraine headaches which targets specific trigger sites. This works on the same principle as migraine surgery, temporarily paralyzing muscles which are compressing nerves. Hence this treatment may work for the trigger sites in the forehead, temple and back of the head, but is ineffective for the nasal trigger site. If you have had a botox injection for migraine and experienced relief, it is highly likely that surgery will benefit you as well.
